

Powerhouse Telemark

The energy sector and the construction industry together account for over 40% of global heat storage emissions. As the world's population and the severity of the climate crisis continue to increase, architects are faced with the challenge of building more responsibly. One such example is the Powerhouse Telemark by Snohetta Architects, completed in August this year. It is an energy-positive building that generates more clean and renewable energy throughout its life cycle than is produced during the production of building materials, construction, operation and demolition. In this video, the cooperation partners of the project explain the innovative ideas.
